

Some Simple Criteria for Gauged R-parity

STEPHEN P. MARTIN[†]

ABSTRACT: We catalog some simple conditions which are sufficient to guarantee that R-parity survives as an unbroken gauged discrete subgroup of the continuous gauge symmetry in certain supersymmetric extensions of the standard model.

[†]Address after Sept. 1, 1992: Dept. of Physics, Northeastern University, Boston MA 02115

Low energy $N = 1$ supersymmetry has been proposed as a cure for the fine-tuning problem associated with the Higgs scalar boson[1]. However, in the minimal supersymmetric extension of the standard model, proton decay might be expected to occur at an unacceptable rate due to the virtual exchange of the superpartners of the standard model states[2,3]. To see this, we can write all of the renormalizable and gauge-invariant terms which might occur in the superpotential:

$$W = W_1 + W_2 + W_3 \tag{1}$$

$$W_1 = \mu H \bar{H} + y_u Q \bar{H} u + y_d Q H d + y_e L H e \tag{2}$$

$$W_2 = \lambda_1 u d d \tag{3}$$

$$W_3 = \mu' L \bar{H} + \lambda_2 Q L d + \lambda_3 L L e \tag{4}$$

[Here Q and L are chiral superfields for the SU_2^L -doublet quarks and leptons; u , d , e are chiral superfields for the SU_2^L -singlet quarks and leptons, and H , $\bar{H}$ are the two SU_2^L -doublet Higgs chiral superfields. Family and gauge indices are suppressed. It is possible to eliminate μ' by a suitable rotation among the superfields H and L ; but we choose not to do this because in most extensions of the minimal supersymmetric standard model H and L will not have the same quantum numbers.] The terms in W_1 are just the supersymmetric versions of the usual standard model Yukawa couplings and Higgs mass, and they conserve baryon number (B) and lepton number (L). However, W_2 violates B by one unit and W_3 violates L by one unit. To prevent the proton from decaying in short order, either (λ_1) or $(\mu', \lambda_2, \lambda_3)$ must be very small[4].

The simplest way to save the proton and avoid other phenomenological disasters is to just banish all of the terms occurring in W_2 and W_3 by means of a discrete Z_2 symmetry known as R-parity[2,3]. All of the standard model states are taken to be even under R-parity and their superpartners are taken to be odd. All interactions are required to have even R-parity. This means that particles with odd R-parity are always produced in pairs, and that the lightest particle with odd R-parity must be stable. At the level of the chiral superfields, this may be implemented by assigning $R_p = -1$ to Q, L, u, d, e and $R_p = +1$ to $H, \bar{H}$. (This R_p is trivially related to R-parity by a factor of -1 for fermions

and is usually called matter parity.) Then the terms in W_2 and W_3 are forbidden because they are R_p -odd, while the terms in W_1 are R_p -even and allowed. The R_p symmetry also forbids some B and L -violating operators of dimension five and higher. Other discrete symmetries are possible[5,6,4] which allow some terms from either W_2 or W_3 , as well as different combinations of higher dimension operators violating B and L .

At the level of the minimal supersymmetric standard model, the imposition of R_p , or any other discrete symmetry designed to protect the proton from decay, appears to be quite *ad hoc*. This is no longer necessarily true if one considers extensions of the minimal theory in which the standard model gauge group is embedded in a larger gauge symmetry, even if the additional gauge symmetry is broken. Indeed, R_p actually follows automatically in certain theories with gauged $B - L$ (e.g. some supersymmetric grand unified theories), and moreover can survive the spontaneous breakdown of the continuous gauge invariance to the standard model gauge group. This will occur if certain conditions, which seem to us to be surprisingly mild, are met by the order parameters of the theory. For some reason, this seems to have been underemphasized in the literature. In this paper, we will catalog some of the simple criteria which are sufficient to guarantee that R_p is an unbroken discrete gauge symmetry for various choices of the gauge group, by classifying the possible group transformation properties of the order parameters of the theory as “safe” or “unsafe” for R_p . For our purposes, it is most convenient to note that for each chiral superfield,

$$R_p = (-1)^{3(B-L)} \quad . \quad (5)$$

This strongly suggests that we obtain gauged R_p as the discrete remnant of a gauged U_1^{B-L} . In fact, with the U_1^{B-L} assignments $Q \sim 1/3$; $L \sim -1$; $u, d \sim -1/3$; $e \sim 1$; and $H, \bar{H} \sim 0$, it is clear that unbroken U_1^{B-L} forbids each of the terms in W_2 and W_3 . To guarantee that R_p should remain unbroken even after U_1^{B-L} is broken, it is necessary and sufficient to require that all Higgs vacuum expectation values (or other order parameters) carry $3(B - L)$ charges which are even integers[7,6]. Following the general arguments of Krauss and Wilczek[8], U_1^{B-L} then breaks down to a gauged Z_2 subgroup which, in view of (5), is nothing other than R_p . Unlike a global symmetry, such a gauged discrete symmetry

will be respected by Planck-scale physics[8].

The most natural setting for gauged U_1^{B-L} occurs in the Pati-Salam unification of color and lepton number: $SU_4^{PS} \supset SU_3^C \times U_1^{B-L}$. Under the gauge group $SU_4^{PS} \times SU_2^L \times U_1^R$, the standard model quark and lepton superfields transform as $Q, L \sim (\mathbf{4}, \mathbf{2}, 0)$ and $d, e \sim (\bar{\mathbf{4}}, \mathbf{1}, 1/2)$ and $u, N \sim (\bar{\mathbf{4}}, \mathbf{1}, -1/2)$. [Here N is the superfield for a neutrino which transforms as a singlet under the standard model gauge group.] With unbroken SU_4^{PS} , the couplings λ_1 , λ_2 , and λ_3 clearly vanish by gauge invariance, since the SU_4^{PS} direct products $\bar{\mathbf{4}} \times \bar{\mathbf{4}} \times \bar{\mathbf{4}}$ and $\mathbf{4} \times \mathbf{4} \times \bar{\mathbf{4}}$ contain no singlets[9]. Also, gauge invariance of the allowed Yukawa couplings in W_1 requires that H transforms as a linear combination of $(\mathbf{1}, \mathbf{2}, -1/2)$ and the color singlet part of $(\mathbf{15}, \mathbf{2}, -1/2)$, and that $\bar{H}$ transforms as a linear combination of $(\mathbf{1}, \mathbf{2}, 1/2)$ and the color singlet part of $(\mathbf{15}, \mathbf{2}, 1/2)$. It then follows that μ' vanishes as well, because it is not allowed by SU_4^{PS} . So unbroken SU_4^{PS} prohibits the same terms in W_2 and W_3 that R_p does. This is hardly a surprise, since R_p is a discrete subgroup of U_1^{B-L} which is contained in SU_4^{PS} .

Of course, SU_4^{PS} and U_1^{B-L} must be broken if we are to obtain the standard model gauge group. To avoid breaking R_p in the process, it is necessary and sufficient that all of the order parameters have even SU_4^{PS} quadrality, since we observe that

$$SU_4^{PS} \text{ quadrality} = 3(B - L) \quad [\text{mod } 4] \quad . \quad (6)$$

Note that the standard model Higgs superfields H and $\bar{H}$ have zero SU_4^{PS} quadrality and thus do not break R_p when they acquire vacuum expectation values. Since the order parameters must also be color singlets, we find that they may transform under SU_4^{PS} as $\mathbf{1}, \mathbf{10}, \mathbf{15}, \mathbf{35} \dots$ and their conjugates, which we refer to as “safe” reps. The order parameters should not occur in “unsafe” reps $\mathbf{4}, \mathbf{20}'', \mathbf{36} \dots$ if we want R_p to survive. In particular, the SU_2^L -singlet order parameters may occur in the “safe” reps $(\mathbf{1}, \mathbf{1}, 0)$; $(\mathbf{10}, \mathbf{1}, 1)$; $(\mathbf{15}, \mathbf{1}, 0)$; $(\mathbf{35}, \mathbf{1}, 2) \dots$ of $SU_4^{PS} \times SU_2^L \times U_1^R$ and their conjugates, but not in the “unsafe” reps $(\mathbf{4}, \mathbf{1}, 1/2)$; $(\mathbf{20}'', \mathbf{1}, -3/2)$; $\dots$ and their conjugates. As long as we arrange for the theory to only have order parameters corresponding to “safe” reps, then R_p remains unbroken.

Actually, $3(B-L)$ is always an integer multiple of 6 for safe order parameters in SU_4^{PS} , since they must also be color singlets. Thus the surviving discrete subgroup of U_1^{B-L} is a Z_6 ; however, a Z_3 subgroup of this is just the discrete center of SU_3^C , which is already taken into account. So the remaining $Z_2 = R_p$ is what really counts. Also note that if all order parameters in the theory had zero SU_4^{PS} quadrality, then because of (6) we would be left with a Z_4 which contains R_p as a subgroup and eliminates certain operators of dimension ≥ 5 which are allowed by R_p . However, such a situation is very unlikely, since obtaining a realistic neutrino mass spectrum via the seesaw mechanism[10] requires a Majorana mass term for N , which in turn requires an order parameter with quadrality 2.

The grand unified theory based on SO_{10} contains SU_4^{PS} as a subgroup, and so we may expect to obtain a nice criterion for this case also. The standard model quark and lepton superfields all transform as components of the 16-dimensional spinor rep of SO_{10} : $Q, L, d, e, u, N \sim \mathbf{16}$. Now the absence of the couplings λ_1 , λ_2 , and λ_3 follows in the language of unbroken SO_{10} from the group theory fact $\mathbf{16} \times \mathbf{16} \times \mathbf{16} \not\supset \mathbf{1}$. Furthermore, since $\mathbf{16} \times \mathbf{16} = \mathbf{10}_S + \mathbf{120}_A + \mathbf{126}_S$, it must be that H and $\bar{H}$ are each linear combinations of appropriate components of $\mathbf{10}$, $\overline{\mathbf{126}}$, and $\mathbf{120}$ (which couples families antisymmetrically) in order to allow the Yukawa couplings in W_1 . Then from $\mathbf{16} \times \mathbf{10} \not\supset \mathbf{1}$, $\mathbf{16} \times \mathbf{120} \not\supset \mathbf{1}$, and $\mathbf{16} \times \overline{\mathbf{126}} \not\supset \mathbf{1}$ it follows that $\mu' = 0$ also for unbroken SO_{10} .

What happens after SO_{10} is broken? The survival or non-survival of R_p just depends on the SO_{10} transformation properties of the order parameters. The relevant property of the SO_{10} reps is the “congruency class”[9] which is defined mod 4. In fact, we find

$$SO_{10} \text{ congruency class} = 3(B-L) \quad [\text{mod } 2], \quad (7)$$

so that “safe” reps for order parameters in SO_{10} are just those with congruency class 0 or 2. The safe reps are $\mathbf{10}$, $\mathbf{45}$, $\mathbf{54}$, $\mathbf{120}$, $\mathbf{126}$, $\mathbf{210}$, $\mathbf{210}'$, $\mathbf{320} \dots$ and their conjugates. The “unsafe” reps are $\mathbf{16}$, $\mathbf{144}$, $\mathbf{560} \dots$ and their conjugates. As long as only order parameters corresponding to even SO_{10} congruency classes are used to break SO_{10} , the resulting low energy gauge group will inevitably include an unbroken R_p . The prospect of removing the unsafe reps for Higgs vacuum expectation values from the model builder’s palette seems

unlamentable; for example[11], SO_{10} can be broken down to $SU_3^c \times SU_2^L \times U_1^Y \times R_p$ with realistic Yukawa couplings and then to $SU_3^c \times U_1^{EM} \times R_p$, using only order parameters in the reps **10**, **54** and $\overline{\mathbf{126}}$. Order parameters in unsafe reps are incapable of giving any masses to the standard model states (or N) anyway. Note that the safe reps of SU_4^{PS} are precisely the ones which are embedded in safe reps of SO_{10} , since SU_4^{PS} quadrality = SO_{10} congruency class [mod 2].

(While chiral superfields in large reps may ruin the asymptotic freedom of the unified gauge coupling, this need not concern us. The order parameters associated with the large reps may find their place only in a phenomenological description, and may not actually correspond to vacuum expectation values for fundamental fields. Also, a Landau singularity in the unified gauge coupling is presumeably irrelevant if it occurs at a distance scale shorter than the Planck length.)

Note that gauged U_1^{B-L} does not occur in a pure SU_5 grand unified theory. In fact, with the standard SU_5 assignments $L, d \sim \overline{\mathbf{5}}$ and $Q, u, e \sim \mathbf{10}$, it is clear that unbroken SU_5 allows λ_1 , λ_2 and λ_3 equally, by looking at the standard model content of the SU_5 fact $\overline{\mathbf{5}} \times \overline{\mathbf{5}} \times \mathbf{10} \supset \mathbf{1}$. Furthermore, H consists of some $\overline{\mathbf{5}}$ and some $\overline{\mathbf{45}}$ and $\bar{H}$ consists of some $\mathbf{5}$ and some $\mathbf{45}$; so μ' is also certainly allowed. There is no reason for any of these couplings to vanish in pure SU_5 , in sharp contrast to our other examples.

The case of supersymmetric “flipped” SU_5 [12] is quite different from pure SU_5 since it contains gauged U_1^{B-L} . Under the gauge group $SU_5 \times U_1^f$, the standard model fermions transform as $Q, d, N \sim (\mathbf{10}, 1)$; $L, u \sim (\overline{\mathbf{5}}, -3)$; and $e \sim (\mathbf{1}, 5)$. Naturally, W_2 and W_3 are absent as long as $SU_5 \times U_1^f$ is unbroken, which can be seen as a consequence of the U_1^{B-L} subgroup. When $SU_5 \times U_1^f$ breaks, R_p survives if the order parameters transform as components of certain “safe” reps of $SU_5 \times U_1^f$. Since U_1^f charge = $3(B - L) \bmod 2$, the safe reps are just those which have even integer U_1^f charges in our normalization. These include $(\mathbf{5}, -2)$ and $(\overline{\mathbf{5}}, 2)$; the unsafe reps include $(\mathbf{5}, 3)$ and $(\mathbf{10}, 1)$ and their conjugates. One of the selling points of flipped SU_5 is that the spontaneous symmetry breaking can be accomplished using only Higgs fields in reps no larger than the $(\mathbf{10}, 1)$. However, this

cannot be accomplished if one insists on using only Higgs fields which are safe for R_p . If unbroken R_p exists in such models, it must come from an additional structure (e.g. superstring theory).

The grand unified theory E_6 also contains U_1^{B-L} as a subgroup. However, reps of E_6 cannot be classified as safe or unsafe for R_p , because each irreducible rep contains components with both even and odd values of $3(B-L)$. Since R_p is an abelian discrete subgroup, it will suffice for us to classify superfields and possible order parameters in E_6 according to their transformation properties under the subgroup $SU_3^c \times SU_2^L \times U_1^Y \times U_1^{B-L} \times U_1^X$. (It does not concern us whether this subgroup is actually the unbroken gauge group at any particular stage of symmetry breaking.) The **27** of E_6 transforms under this subgroup as $(\mathbf{3}, \mathbf{2}, 1/6, 1/3, 1) + (\mathbf{1}, \mathbf{2}, -1/2, -1, 3) + (\bar{\mathbf{3}}, \mathbf{1}, -2/3, -1/3, 2) + (\bar{\mathbf{3}}, \mathbf{1}, 1/3, -1/3, 2) + (\mathbf{1}, \mathbf{1}, 1, 1, 0) + (\mathbf{1}, \mathbf{1}, 0, 1, 0) + (\bar{\mathbf{3}}, \mathbf{1}, 1/3, 2/3, -4) + (\mathbf{3}, \mathbf{1}, -1/3, -2/3, -2) + (\mathbf{1}, \mathbf{2}, 1/2, 0, -3) + (\mathbf{1}, \mathbf{2}, -1/2, 0, -3) + (\mathbf{1}, \mathbf{1}, 0, 0, 6)$. This defines U_1^X , which may be thought of as the extra U_1 which occurs in E_6 but not SO_{10} . The first five terms may be identified with Q , L , u , d , and e respectively. (We assume that each of the three standard model families are embedded in the **27** in the same way.) It then follows that H and $\bar{H}$ transform as $(\mathbf{1}, \mathbf{2}, -1/2, 0, -3)$ and $(\mathbf{1}, \mathbf{2}, 1/2, 0, -3)$. With these assignments, the Yukawa terms in W_1 all transform as $(\mathbf{1}, \mathbf{1}, 0, 0, 0)$ and the terms udd , QLd and LLe in W_2 and W_3 each transform as $(\mathbf{1}, \mathbf{1}, 0, -1, 6)$. The term $L\bar{H}$ in W_3 transforms as $(\mathbf{1}, \mathbf{1}, 0, -1, 0)$. Note that an order parameter $(\mathbf{1}, \mathbf{1}, 0, 0, 6)$ is necessary so that the non-standard-model particles $(\bar{\mathbf{3}}, \mathbf{1}, 1/3, 2/3, -4) + (\mathbf{3}, \mathbf{1}, -1/3, -2/3, -2)$ can get masses, and to allow $H\bar{H}$ in W_1 . We now classify as safe or unsafe the possible $\Delta I = 0$ and $\Delta I = 1/2$ order parameters which occur in the smallest few reps of E_6 , namely the **27**, **78**, **351**, and **351'**. (Safe and unsafe reps in $\bar{\mathbf{27}}$, $\bar{\mathbf{351}}$ and $\bar{\mathbf{351}}'$ can be found by conjugating the ones below.)

The $\Delta I = 0$ order parameters for E_6 which are safe for unbroken R_p are: $(\mathbf{1}, \mathbf{1}, 0, 0, 0)$, which occurs three times in the **78** of E_6 ; $(\mathbf{1}, \mathbf{1}, 0, 0, -12)$, which occurs once in the **351'**; $(\mathbf{1}, \mathbf{1}, 0, 0, 6)$, which occurs once in the **27**, twice in the **351**, and once in the **351'**; and $(\mathbf{1}, \mathbf{1}, 0, -2, 0)$, which occurs once in the **351'**. The unsafe $\Delta I = 0$ order parameters for E_6 are: $(\mathbf{1}, \mathbf{1}, 0, -1, 6)$ and $(\mathbf{1}, \mathbf{1}, 0, 1, -6)$, which each occur once in the **78**; $(\mathbf{1}, \mathbf{1}, 0, 1, 0)$,

which occurs once in the **27**, twice in the **351**, and once in the **351'**; and $(\mathbf{1}, \mathbf{1}, 0, -1, -6)$, which occurs once in the **351** and once in the **351'**.

The safe $\Delta I = 1/2$ order parameters for E_6 transform according to: $(\mathbf{1}, \mathbf{2}, 1/2, 0, -3)$ and $(\mathbf{1}, \mathbf{2}, -1/2, 0, -3)$, which each occur once in the **27**, three times in the **351** and twice in the **351'**. The unsafe $\Delta I = 1/2$ reps include $(\mathbf{1}, \mathbf{2}, 1/2, 1, 3)$ and $(\mathbf{1}, \mathbf{2}, -1/2, -1, -3)$ which each occur once in the **78**; $(\mathbf{1}, \mathbf{2}, -1/2, -1, 3)$ which occurs once in the **27**, three times in the **351**, and twice in the **351'**; $(\mathbf{1}, \mathbf{2}, 1/2, 1, -9)$, $(\mathbf{1}, \mathbf{2}, 1/2, -1, 3)$ and $(\mathbf{1}, \mathbf{2}, -3/2, -1, 3)$ which each occur once in the **351** and once in the **351'**.

Now, using safe $\Delta I = 0$ order parameters listed above for **27**, **351** and **351'**, E_6 can be broken down to $SU_3^C \times SU_2^L \times U_1^Y \times R_p$ and the states other than Q, L, u, d, e in the **27** are all eligible to obtain large masses. Also, safe order parameters for $(\mathbf{1}, \mathbf{2}, 1/2, 0, -3)$ and $(\mathbf{1}, \mathbf{2}, -1/2, 0, -3)$ provide for standard model masses. So, the statement for E_6 is that the safe reps for order parameters correspond to those which are necessary anyway to break E_6 to the standard model with the correct mass spectrum. Order parameters in the unsafe reps are not needed for anything from this point of view, although demanding their absence would eliminate some otherwise attractive symmetry breaking patterns.

Dimension-five operators which violate B and L can also contribute to proton decay. The only such operators consistent with supersymmetry and the standard model gauge group which are not already forbidden by R_p are $[uude]_F$, $[QQQL]_F$ and $[LL\bar{H}\bar{H}]_F$. The first two of these terms are also allowed by any gauge invariance contained in SO_{10} , in view of the standard model content of the group theory fact $\mathbf{16} \times \mathbf{16} \times \mathbf{16} \times \mathbf{16} \supset \mathbf{1} + \mathbf{1}$. However, all three terms (and $H\bar{H}$ in W_1) are prohibited by unbroken E_6 because of $\mathbf{27} \times \mathbf{27} \times \mathbf{27} \times \mathbf{27} \not\supset \mathbf{1}$, etc.; this is a simple consequence of E_6 triality[9], since $Q, L, u, d, e, H, \bar{H}$ all must have triality 1. Or, it may be viewed as a consequence of U_1^X and U_1^{B-L} conservation. The fact that these terms are forbidden by an unbroken E_6 gauge group may provide a means of suppressing them even more heavily than naive expectation in the low energy theory, although the extent to which this is true is model dependent. The order parameter $(\mathbf{1}, \mathbf{1}, 0, 0, 12)$ breaks U_1^X to a Z_{12} without allowing the aforementioned terms. An order

parameter $(\mathbf{1}, \mathbf{1}, 0, 0, 6)$, which is presumably necessary as noted earlier, will further break U_1^X to a Z_6 and allow $[uude]_F$, $[QQQL]_F$ and $[H\bar{H}]_F$. This Z_6 is nothing new, because it is just a subgroup of $Z_3^C \times Z_2^L$, where Z_3^C is the center of SU_3^C and Z_2^L is the center of SU_2^L . The order parameter $(\mathbf{1}, \mathbf{1}, 0, -2, 0)$ breaks U_1^{B-L} to R_p and allows $[LL\bar{H}\bar{H}]_F$.

If R_p -unsafe order parameters do occur in theories with gauged U_1^{B-L} , then R_p is spontaneously broken. This is not necessarily a disaster if the mass scales of the unsafe order parameters are sufficiently small compared to the unification scale. One popular example which has been explored in the literature[13] involves spontaneous R_p breaking due to an expectation value for the scalar partner of a neutrino which transforms in the unsafe rep $(\mathbf{1}, \mathbf{1}, 0, 1, 0) \subset \mathbf{27}$ of $SU_3^C \times SU_2^L \times U_1^Y \times U_1^{B-L} \times U_1^X \subset E_6$, or the unsafe rep $\mathbf{16}$ of SO_{10} . There are, of course, other possible examples (of problematical phenomenological viability) for spontaneously broken R_p if other unsafe reps listed above obtain vacuum expectation values. The dominant contributions to B and L -violating terms in the low energy effective superpotential come from tree graphs with unsafe order parameters on external legs. Note that explicit R_p breaking is really a contradiction in terms for any model with gauged U_1^{B-L} , because of (5); it must be either exact or spontaneously broken.

In superstring-inspired models based on remnants of E_6 , the existence of R_p depends on e.g. the properties of the six-dimensional compactified manifold. There are a bewildering plethora of possibilities for the vacuum, some of which respect R_p or other generalized matter parities, and some of which do not. Note that it is not possible to break the U_1^{B-L} subgroup to R_p in these models *after* compactification, because the necessary safe order parameter resides in the $\mathbf{351}'$ (or larger) rep of E_6 , and not in the $\mathbf{27}$, $\overline{\mathbf{27}}$, or singlet reps which are available for chiral superfields in the perturbative field theory limit of superstring theory. In such models it is not possible to understand in detail “why” unbroken R_p should exist without understanding the compactification mechanism. In this paper we have considered instead criteria which can be understood using only an effective $N = 1$ supersymmetric model. These criteria are reassuringly not too restrictive, and are especially crisp in the languages of U_1^{B-L} , SU_4^{PS} and SO_{10} . Hopefully, R-parity appears less *ad hoc* in this light.

I am grateful to Pierre Ramond for helpful comments. This work was supported in part by the Institute for Fundamental Theory and by DOE contract DE-FG05-86-ER40272.
